Fragmentation of Chocolate During the First Bite

"A Multiscale Finite Element Analysis Model for Predicting the Effect of Micro-Aeration on the Fragmentation of Chocolate During the First Bite," Georgios Samaras, Dimitrios Bikos, Philippa Cann, Marc Masen, Yannis Hardalupas, Josélio Vieira, Christoph Hartmann, and Maria Charalambides, *European Journal of Mechanics-A/Solids*, vol. 104, no. 1, March 2024, article 105221. The authors, at Imperial College London, UK; Nestlé Product Technology Centre, UK; and Nestlé Research, Switzerland, report:

The micromechanical models are compared to data from literature on mechanical testing of the same two chocolate materials whereas the first-bite macromechanical model was compared to in vitro experimental data obtained in this study using a 3D-printed molar teeth test rig mounted to a mechanical tester. Finally, the particle size distribution of the fragmented chocolate during the first bite was estimated from the in silico model and compared to in vivo literature data on the same chocolate materials and in vitro experimental data from this work. All comparisons between the in silico models and the in vitro/in vivo data led to good agreement.

A multiscale finite element analysis model for predicting the effect of micro-aeration on the fragmentation of chocolate during the first bite

ABSTRACT

The emerging need to reduce the calorific value of foods, while simultaneously improving the consumer perception drives the quest for developing new food structures that satisfy both criteria. Aiming to shed light on the breakdown of chocolate during the early stages of the mastication process, this work explores the development of multi-scale, *in silico* Finite Element (FE) models. A micromechanical analysis was first employed to predict the impact on the mechanical behaviour of the chocolate at different micro-aeration levels, i.e. $f = 10\text{vol}\%$ and $f = 15\text{vol}\%$. The estimated elastic moduli from the micromechanical model were subsequently fed into a macroscopic micromechanical and the macromechanical models for the 10vol% and 15vol% aeration levels. The micromechanical model was able to predict the fragmentation of the chocolate during the first bite, in accordance with the experimental data for validation purposes. The micromechanical model was able to predict the fragmentation of the chocolate during the first bite, in accordance with the experimental data for validation purposes.

Stochastic Mastication of Viscoelastic Fish Sausage

"Fragmentation of a Viscoelastic Food by Human Mastication," Naoki Kobayashi, Kaoru Kohyama, and Kouichi Shiozawa, *Journal of the Physical Society of Japan*, vol. 79, no. 4, 2010, article 044801. (Thanks to Claire Marrache for bringing this to our attention.) The authors, at Chuo University, National Agriculture and Food Research Organization, and Tsurumi University School of Dental Medicine, Japan, report:

Fragment-size distributions have been studied experimentally in masticated viscoelastic food (fish sausage). The mastication experiment in seven subjects was examined....

First, each subject masticated the test food until swallowing as usual to count the number of chewing cycles until swallowing. Next, we calculated the individual number of chewing cycles until the halfway of the mastication. To collect the food bolus at the halfway of the mastication and just before swallowing, subjects were asked to masticate the test food until individually prescribed number of chewing cycles, and they spat the bolus into a beaker. The collection of food bolus was performed two times per subject and each condition. In order to expectorate entirely the subject rinsed their mouth with water. The food fragments and water were carefully stirred in a beaker with a glass rod and pass through a sieve with a mesh size of 0.5 mm. After fine fragments were washed through the sieve with running water, the fragments on the sieve were spread evenly on the transparent acrylic board (300 mm × 300 mm). Then, we made a copy of this board using copy machine (DocuCentral-II, FUJI XEROX, JAPAN) without cover and stored the copy on a personal computer at a suitable resolution (about 0.13 mm/pixel).

Fragmentation of a Viscoelastic Food by Human Mastication

(Received October 1, 2009; accepted February 15, 2010; published April 12, 2010)

Fragment-size distributions have been studied experimentally in masticated viscoelastic food (fish sausage). The mastication experiment in seven subjects was examined. We classified the obtained results into two groups, namely, a single lognormal distribution and a lognormal distribution with exponential tail group. The facts suggest that the individual variability might affect the fragmentation pattern when the food sample has a much more complicated physical property. In particular, the latter result shows a distribution with a long tail, indicating that the fragmentation pattern has

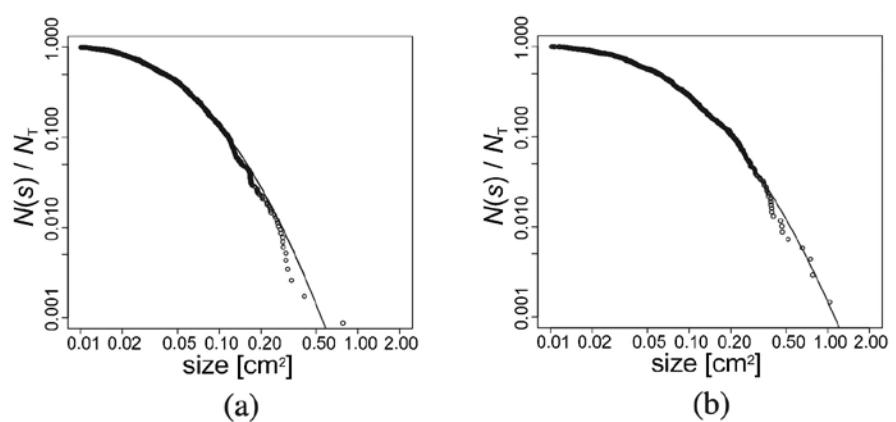

Fig. 1. Log-log plots for the cumulative number of masticated food fragments of fish sausage after (a) 32 and (b) 16 chews. The solid line indicates a lognormal distribution for (a) $N_T = 1161$, $\bar{s} = 0.0375$, $\sigma = 0.859$, and $N/N_T = 1.08$, and (b) $N_T = 688$, $\bar{s} = 0.0559$, $\sigma = 0.965$, and $N/N_T = 1.04$.

Who Put the Toothbrushes in the Digestive Tract

“Toothbrush Swallow: A Scoping Review,” Mahomed Sidique Abdul Cadar Dadá, Abdul Habib Mahomed Dadá, and Zulaikhah Mahomed Sidique Dadá, *Brazilian Journal of Clinical Medicine and Review*, vol. 2, no. 2, 2024, pp. 42-53. The authors, at Universidade Eduardo Mondlane, DentalCare Professional Training Center, and Eduardo Mondlane University, Mozambique, report:

[T]he ingestion of a toothbrush is very rare and, because it is large, it entails potential complications. The objective of the present study was to investigate, through a scoping review, the etiology of toothbrush ingestion. This review intends to describe all clinical cases of toothbrush ingestion mentioned in the main databases. Initially... toothbrush swallow is rare. In this study it was found that most cases of toothbrush ingestion were intentional (bulimia, induction of vomiting and mental disorder) and the toothbrushes that appear in the gastrointestinal tract are placed by the patients accidentally or intentionally and rarely by someone else.

Abstract: The ingestion of foreign bodies is a frequent problem in the emergency services of hospitals, but the ingestion of a toothbrush is very rare and, because it is large, it entails potential complications. The objective of the present study was to investigate, through a scoping review, the etiology of toothbrush ingestion. This review intends to describe all clinical cases of toothbrush ingestion mentioned in the main databases. Initially, 136 studies were selected, 31 duplicate studies

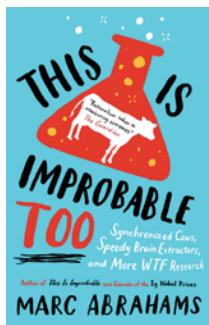

and 105 studies were excluded, leaving 20 studies for the final analysis.

Table 3. Anatomical location of Swallowed Toothbrush.

Location	n	%
Pharynx	3	8,1
Esophagus	4	10,8
Stomach	23	62,2
Duodenum	2	5,4
Ileum	1	2,7
Colon	2	5,4
Parapharyngeal space	1	2,7
Neck	1	2,7
Total	37	100,0
